Mars Pathfinder Incident

- Landing on July 4, 1997
- “experiences software glitches”
- Pathfinder experiences repeated RESETS after starting gathering of meteorological data.
- RESETS generated by watchdog process.
- Timing overruns caused by priority inversion.
- Resources:
 - `research.microsoft.com/~mbj/Mars_Pathfinder/Mars_Pathfinder.html`

Resource Access: System Model

Processor(s) and Resources

- m types of serially reusable resources R_1, \dots, R_m
- An execution of a job J_i requires:
 - a processor for e_i units of time
 - some resources for exclusive use

Resources

- **Serially Reusable:** Allocated to one job at a time. Once allocated, held by the job until no longer needed.
- Examples: semaphores, locks, servers, ...
- Operations:
 - `lock(Ri)` -----<critical section>----- `unlock(Ri)`
- Resources allocated non-preemptively
- Critical sections properly nested

© R. Bettati

Preemption of Tasks in their Critical Sections

Example:

- Negative effect on schedulability and predictability.
- Traditional resource management algorithms fail (e.g. Banker's Algorithm). They decouple resource management decisions from scheduling decisions.

© R. Bettati

Unpredictability: Scheduling Anomalies

- Example: $T_1 = (c_1=2, e_1 = 5, p_1 = 8)$ $T_2 = (4, 7, 22)$ $T_3 = (4, 6, 26)$

- Shorten critical section of T_3 :

$$T_1 = (c_1=2, e_1 = 5, p_1 = 8) \quad T_2 = (4, 7, 22) \quad T_3 = (2.5, 6, 26)$$

Possible Solution: Disallow Processor Preemption of Tasks in Critical Section [A. Mok]

- Analysis identical to analysis with non-preemptable portions
- Define: β = maximum duration of all critical sections
- Task T_i is schedulable if

$$\sum_{k=1}^i \frac{e_k}{p_k} + \frac{\beta}{p_i} \leq U_X(i)$$

X : scheduling algorithm

- **Problem:** critical sections can be rather long.

Possible Solution: Priority Inheritance

© R. Bettati

Terminology

- A job is **directly blocked** when it requests a resource R_i , i.e. executes a **lock(R_i)**, but no resource of type R_i is available.
- Job J' **directly blocks** J if J' holds some resources that J has requested.
- The scheduler **grants the lock request**, i.e. allocates the requested resource to the job, according to the **resource allocation rules**, as soon as the resources become available.
- **New forms of blocking** (e.g. “blocking through inheritance”) may be introduced by the resource management policy to control priority inversion and/or prevent deadlocks.

© R. Bettati

Basic Priority-Inheritance Protocol

- **Jobs that are not blocked** are scheduled according to a priority-driven algorithm preemptively on a processor.
- Priorities of tasks are fixed, except for the conditions described below:
 - A job J requests a resource R by executing **lock(R)**
 - If R is available, it is allocated to J . J then continues to execute and releases R by executing **unlock(R)**
 - If R is allocated to J' , J' **directly blocks** J . The request for R is denied.
 - However: Let
 - π = priority of J when executing **lock(R)**
 - π' = priority of J' at the same time
 - For as long as J' holds R , its priority is $\max(\pi, \pi')$ and returns to π' when it releases R .
 - That is: J' **inherits** the priority of J when J' directly blocks J , and J has a higher priority.
- Priority Inheritance is **transitive**.

© R. Bettati

Example: Priority Inheritance Protocol

$$\pi_1 > \pi_2 > \pi_3 > \pi_4 > \pi_5$$

Task uses A Task uses A and B Task uses B

Problem: If T_5 tries to **lock(B)** while it has priority π_1 , we have a **deadlock!**

© R. Bettati

Example: Priority Inheritance Protocol (2)

$$\pi_1 > \pi_2 > \pi_3 > \pi_4 > \pi_5$$

Task uses A Task uses A and B Task uses B

Problem: If T_5 tries to **lock(B)** while it has priority π_1 , we have a **deadlock!**

© R. Bettati

Properties of Priority Inheritance Protocol

1. Priority Inheritance does **not prevent deadlock**.
2. Task can be **blocked directly** by a task with a lower priority **at most once**, for the duration of the (**outmost**) critical section.

Consider a task whose priority is higher than n other tasks:

- Each of the lower-priority tasks can **directly** block the task **at most once**.
- A task **outside** the critical section **cannot** directly block a higher-priority task.

Priority Ceiling Protocol

- Assumptions:
 - Priorities of tasks are fixed
 - Resources required by tasks are known
- Definition (Priority Ceiling of R)
Priority Ceiling Π_R of R = highest priority of all tasks that will request R .
- Any task holding R may have priority Π_R at some point; either its own priority is Π_R , or it inherits Π_R .
- Motivation:
 - Suppose there are resource A and B .
 - Both A and B are available. T_1 requests A .
 - T_2 requests B after A is allocated.
 - If $\pi_2 > \Pi_A$: T_1 can never preempt $T_2 \Rightarrow B$ should be allocated to T_2 .
 - If $\pi_2 \leq \Pi_A$: T_1 can preempt T_2 (and also request B) at some later time. B should not be allocated to T_2 , to avoid deadlock.

© R. Bettati

Priority Ceiling Protocol (II)

- Same as the basic Priority Inheritance Protocol, except for the following:
- When a task T requests for allocation of a resource R by executing **lock(R)**:
 - The request is denied if
 1. Resource R already allocated to T' . (T' directly blocks T)
 2. The priority of T is not higher than all priority ceilings of resources allocated to tasks *other than* T at the time. (These tasks block T .)
 - Otherwise, R is allocated to T .
- When a task blocks other tasks, it inherits the highest of their priorities.

© R. Bettati

Priority Ceiling Protocol: Example

[Lehoczky et al., 1990]

T_1	T_2	T_3
-	-	-
-	-	-
lock (X)	-	lock (Y)
-	lock (Z)	-
-	-	-
unlock (X)	-	lock (Z)
-	lock (Y)	-
-	unlock (Y)	unlock (Z)
-	-	unlock (Y)
-	unlock (Z)	-

© R. Bettati

Priority Ceiling Protocol: Example II

- (*) Fails: directly blocked by T_5
- (**) Fails: $\pi_4 < \Pi_A$
- (1) T_5 blocks T_4 (to prevent deadlock)
- (2) T_5 blocks T_3 (to control priority inversion)

$\pi_1 > \pi_2 > \pi_3 > \pi_4 > \pi_5$
 $\Pi_A = \pi_2, \Pi_B = \pi_1$

© R. Bettati

Schedulability Analysis of PCP: Reminders

Recall: **Blocking**: A higher-priority task waits for a lower-priority task.

A task T_H can be blocked by a lower-priority task T_L in **three ways**:

Direct Blocking:

Blocking due to Priority Inheritance: T_L inherits a priority higher than the priority π_H of T_H .

Blocking due to Priority Ceiling: T_H requests a resource and the priority ceiling of resources held by T_L is equal to or higher than π_H :

© R. Bettati

Sched. Analysis of PCP: Preliminary Observations

- Consider: Task T with priority π and release time t .
- Define: **Current Priority Ceiling** $\Pi(t)$: Highest priority ceiling of all resources allocated at time t .

Preliminary Observation 1:

T cannot be blocked if at time t , every resource allocated has a priority ceiling less than π , i.e., $\pi > \Pi(t)$.

- Obvious:
 - **No direct blocking**: T will not require any of the resources allocated at time t with priority ceilings $< \pi$, and will not be directly blocked waiting for them.
 - **No inheritance blocking**: No lower-priority task can inherit a priority higher than π through resources allocated at time t .
 - **No priority ceiling blocking**: No task with priority lower than π holds any resource with priority ceiling $\geq \pi$.
 - Ergo: **No blocking at all!** Requests for resources by T will not be denied because of resource allocations made before t .

© R. Bettati

Sched. Analysis of PCP: Preliminary Observations (II)

Preliminary Observation 2

Suppose that

1. there is a task T_L holding a resource X
2. T (with priority π) preempts T_L , and then
3. T is allocated a resource Y .

Until T completes, T_L cannot inherit a priority higher or equal to π .

- Reason: (π_L = priority of T_L when it is preempted.)
 - $\pi_L < \pi$
 - T is allocated a resource
 - $\Rightarrow \pi$ is higher than all the priority ceilings of resources held by all lower-priority tasks when T preempts T_L .
 - T cannot be blocked by T_L , from Preliminary Observation 1.
 - $\Rightarrow \pi_L$ cannot be raised to π or higher through inheritance.

© R. Bettati

Schedulability Analysis of PCP

- Reminder: Critical sections are properly nested
 - \Rightarrow Duration of a critical section equals the **outmost** critical section.

Observation 1:

A low-priority task T_L can block a higher-priority task T_H **at most once**.

- Reason: When T_L is **not** in critical section:
 - $\pi_L < \pi_H$, and
 - T_L cannot inherit a higher priority

© R. Bettati

Schedulability Analysis of PCP (II)

Observation 2

A task T can be blocked for at most the duration of one critical section, no matter how many tasks share resources with T .

- Reason:
 - It is not possible for T to be blocked for durations of 2 critical sections of the same task.
 - It is not possible for T to be blocked by T_1 and T_2 with priorities $\pi_1 < \pi$, $\pi_2 < \pi$.

© R. Bettati

Schedulability Analysis of PCP (III)

Observation 3:

The Priority Ceiling Protocol prevents transitive blocking. i.e., the blocking graph cannot contain a subgraph of the form:

- If such a subgraph were to exist, we must have:
 - Tasks assigned priorities must satisfy $\pi_1 > \pi_2 > \pi_3$.
 - Two or more resources are involved; the TWF-Graph must contain the following subgraph, for two resources X and Y :

- Task T_3 must be allocated Y , then T_2 is allocated X .
- From Preliminary Observation 2: "Until T_2 completes, it is not possible for T_3 to inherit a priority higher than π_2 ."
- According to the above subgraph, T_3 inherits $\pi_1 > \pi_2$.

\Rightarrow CONTRADICTION!

© R. Bettati

Schedulability Analysis of PCP (IV)

Observation 4:

The Priority Ceiling Protocol prevents deadlocks.

- Transitive blocking is not possible (Observation 3).
- Therefore, it suffices to show that the blocking graph (or the TWF-Graph) cannot contain cycles of length 2.
- i.e. subgraphs of the form

Stack Sharing

- Sharing of the stack among tasks eliminates stack space fragmentation and so allows for memory savings:

no stack sharing

stack sharing

- However:
 - Once job is preempted, it can only resume when it returns to be on top of stack.
 - Otherwise, it may cause a deadlock.
 - Stack becomes a resource that allows for “one-way preemption”.

© R. Bettati

Stack-Sharing Priority-Ceiling Protocol

- To avoid deadlocks: Once execution begins, make sure that job is not blocked due to resource access.
- Otherwise: Low-priority, preempted, jobs may re-acquire access to CPU, but can not continue due to unavailability of stack space.
- Define: $\Pi(t)$: highest priority ceiling of all resources currently allocated.
If no resource allocated, $\Pi(t) = \infty$.

Protocol :

1. **Update Priority Ceiling**: Whenever all resources are free, $\Pi(t) = \infty$. The value of $\Pi(t)$ is updated whenever resource is allocated or freed.
2. **Scheduling Rule**: After a job is released, it is blocked from starting execution until its assigned priority is higher than $\Pi(t)$.
At all times, jobs that are not blocked are scheduled on the processor in a priority-driven, preemptive fashion according to their assigned priorities.
3. **Allocation Rule**: Whenever a job requests a resource, it is allocated the resource.

© R. Bettati

Stack-Based Priority-Ceiling Protocol (cont)

- The Stack-Based Priority-Ceiling Protocol is **deadlock-free**:
 - When a job begins to execute, all the resources it will ever need are free.
 - Otherwise, $\Pi(t)$ would be higher or equal to the priority of the job.
 - Whenever a job is preempted, all the resources needed by the preempting job are free.
 - The preempting job can complete, and the preempted job can resume.
- **Worst-case blocking time** of Stack-Based Protocol is the same as for Basic Priority Ceiling Protocol.
- Stack-Based Protocol smaller **context-switch overhead** (2 CS) than Priority Ceiling Protocol (4 CS)
 - Once execution starts, job cannot be blocked.

© R. Bettati

Ceiling-Priority Protocol

- Stack-Based Protocol **does not allow for self-suspension**
 - Stack is shared resource
- Re-formulation for multiple stacks (no stack-sharing) straightforward:

Ceiling-Priority Protocol

Scheduling Rules:

1. Every job executes at its assigned priority when it does not hold resources.
2. Jobs of the same priority are scheduled on FIFO basis.
3. Priority of jobs holding resources is the highest of the priority ceilings of all resources held by the job.

Allocation Rule:

- Whenever a job requests a resource, it is allocated the resource.

Priority-Ceiling Locking in Ada 9X

[Ada 9X; RT Annex]

- Task definitions allow for a **pragma** Priority as follows:
`pragma Priority(expression)`
- Task priorities:
 - **base priority**: priority defined at task creation, or dynamically set with `Dynamic_Priority.Set_Priority()` method.
 - **active priority**: base priority or priority inherited from other sources (activation, rendez-vous, protected objects).
- Priority-Ceiling Locking:
 - Every **protected object** has a **ceiling priority**: Upper bound on active priority a task can have when it calls a protected operation on objects.
 - While task executes a protected operation, it inherits the ceiling priority of the corresponding protected object.
 - When a task calls a protected operation, a check is made that its active priority is not higher than the ceiling of the corresponding protected object.
 - A **Program Error** is raised if this check fails.

© R. Bettati

Priority-Ceiling Locking in Ada 9X: Implementation

[Ada 9X; RT Annex]

- Efficient implementation possible that **does not rely on explicit locking**.
- Mutual exclusion is enforced by priorities and priority ceiling protocol only.
- We show that Resource R can never be requested by Task T_2 while it is held by Task T_1 .
- Simplified argument (AP = "Active Priority"):
 - $AP(T_2)$ can never be higher than $C(R)$. Otherwise, run-time error would occur. $\Rightarrow AP(T_2) \leq C(R)$
 - As long as T_1 holds R , it cannot be blocked.
 - Therefore, for T_2 to request R after T_1 seized it, T_1 must have been preempted (priority of T_1 does not change while T_1 is in ready queue).
 - For T_2 to request R while T_1 is in ready queue, T_2 must have higher active priority than T_1 . $\Rightarrow AP(T_2) > AP(T_1)$
 - T_1 is holding R $\Rightarrow C(R) \leq AP(T_1) < AP(T_2)$
 - Before T_2 requests R , T_2 's priority must drop to $\leq C(R)$
 - Case 1: $AP(T_2)$ drops to below $AP(T_1) \Rightarrow T_2$ preempted
 - Case 2: $AP(T_2)$ drops to $AP(T_1) \Rightarrow T_2$ must yield to T_1 (by rule)

© R. Bettati
