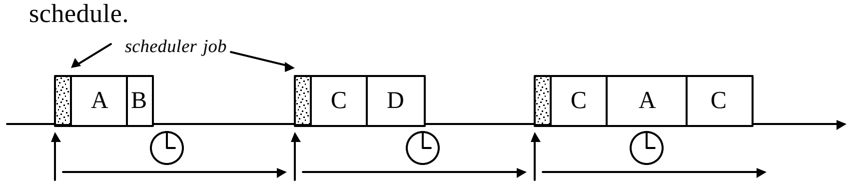
Common Approaches to Real-Time Scheduling

- **Clock-driven** (time-driven) schedulers
  - Scheduling decisions are made at *specific time instants*, which are typically chosen *a priori*.
- **Priority-driven** schedulers
  - Scheduling decisions are made when particular events in the system occur, *e.g.*
    - a job becomes available
    - processor becomes idle
  - **Work-conserving**: processor is busy whenever there is work to be done.

Clock-Driven (Time-Driven) -- Overview

- **Scheduling decision time**: point in time when scheduler decides which job to execute next.
- Scheduling decision time in clock-driven schedulers is defined *a priori*.
- For example: Scheduler periodically wakes up and generates a portion of the schedule.



- Special case: When job parameters are known *a priori*, schedule can be precomputed off-line, and stored as a table (table-driven schedulers).

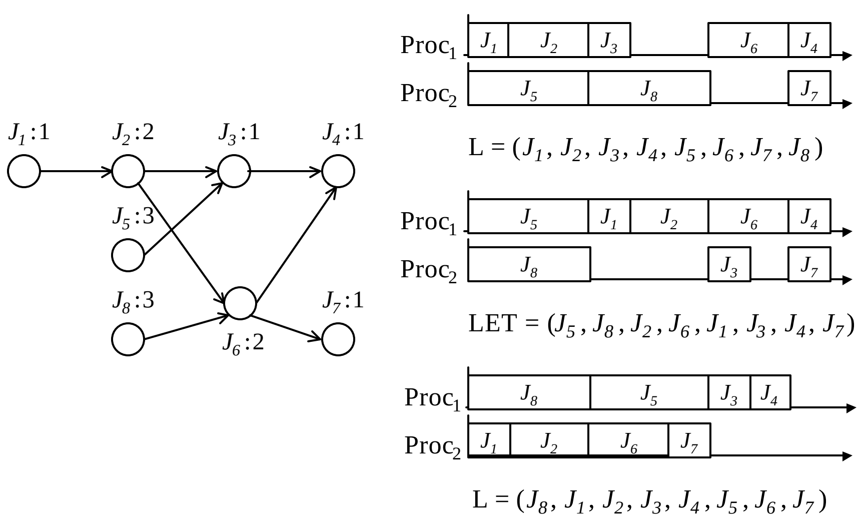
Priority-Driven -- Overview

- Basic rule: Never leave processor idle when there is work to be done. (such schedulers are also called **work conserving**)
- Based on list-driven, greedy scheduling.
- Examples: FIFO, LIFO, SET, LET, EDF.

- Possible **implementation** of preemptive priority-driven scheduling:
  - Assign priorities to jobs.
  - Scheduling decisions are made when
    - Job becomes ready
    - Processor becomes idle
    - Priorities of jobs change
  - At each scheduling decision time, chose ready task with highest priority.

- In non-preemptive case, scheduling decisions are made only when processor becomes idle.

Example: Priority-Driven Non-Preemptive Schedules



Effective Timing Constraints

- Timing constraints often inconsistent with precedence constraints.
  Example: $d_1 > d_2$, but $J_1 < J_2$
- Effective timing constraints on single processor:
- Effective release time: $r_i^{eff} := \max\left(r_i, \left\{r_j^{eff} \middle| J_j < J_i\right\}\right)$
- Effective deadline: $d_i^{eff} := \min\left(d_i, \left\{d_j^{eff} \middle| J_i < J_j\right\}\right)$
- Theorem: A set of Jobs ***J*** can be feasibly scheduled on a processor if and only if it can be feasibly scheduled to meet all effective release times and deadlines.

Interlude: The EDF Algorithm

- The EDF (earliest-deadline-first) algorithm:
  At any time, execute that available job with the earliest deadline.
- Theorem: **(Optimality of EDF)** In a system one processor and with preemptions allowed, EDF can produce a feasible schedule of a job set ***J*** with arbitrary release times and deadlines *iff* such a schedule exists.
- Proof: by schedule transformation.

EDF Not Always Optimal

- Case 1: When preemption is not allowed:

	r_i	d_i	e_i
J_1 = (	0,	10,	3)
J_2 = (	2,	14,	6)
J_3 = (	4,	12,	4)

- Case 1: On more than one processor:

	r_i	d_i	e_i
J_1 = (	0,	4,	1)
J_2 = (	0,	4,	1)
J_3 = (	0,	5,	5)
