-

Simple Electronic Circuit: RC Cell

- Output $y(t)$ of this circuit is convolution of input $x(t)$ and impulse response $h(t)$ of circuit.

- Impuls response:
$$h(t) = \frac{1}{RC} e^{(-t/RC)} \quad t \geq 0$$

- Output:
$$y(t) = (h \otimes x)(t) = \int_0^t h(t-s)x(s)ds$$
-

Greedy Shaper

- A shaper forces an input traffic flow $x(t)$ to have an output $y(t)$ which adheres to an envelope σ .
- The output function $y(t)$ can be derived as follows:

$$y(t) = (\sigma \otimes x)(t) = \inf_{0 \leq s \leq t} \{ \sigma(t-s) + x(s) \}$$

- Other analogies apply as well (commutativity and associativity), which allow to extend this analysis to large-scale systems.
 - There are significant differences, though!
-

Min-Plus Calculus: Infimum vs. Minimum

- Let S be nonempty subset of \mathcal{R} .

Definition [Infimum]

$$\begin{aligned} \inf(S) &= (M \text{ s.t. } s \geq M \forall s \in S) \\ \inf(\emptyset) &= +\infty \end{aligned}$$

Definition [Minimum]

$$\min(S) = (\underline{M} \in S \text{ s.t. } s \geq M \forall s \in S)$$

- Notation: \wedge denotes infimum (e.g. $a \wedge b = \min\{a, b\}$)
-

The Dioid $(\mathcal{R} \cup \{+\infty\}, \wedge, +)$

- Conventional (“plus-times”) algebra operates on algebraic structure $(\mathcal{R}, +, *)$.
- Min-plus algebra replaces operations:
 - “addition” becomes “computation of infimum”
 - “multiplication” becomes “addition”
- Resulting algebraic structure becomes $(\mathcal{R} \cup \{+\infty\}, \wedge, +)$
- Example:
 - Conventional algebra: $(3+4) * 5 = (3*5) + (4*5) = 15 + 20$
 - min-plus algebra: $(3 \wedge 4) + 5 = (3 + 5) \wedge (4 + 5) = 8 \wedge 9 = 8$

Properties of $(\mathcal{R} \cup \{+\infty\}, \wedge, +)$

- **(Closure of \wedge)** For all $a, b \in \mathcal{R} \cup \{+\infty\}$, $a \wedge b \in \mathcal{R} \cup \{+\infty\}$
- **(Associativity of \wedge)** For all $a, b, c \in \mathcal{R} \cup \{+\infty\}$, $(a \wedge b) \wedge c = a \wedge (b \wedge c)$
- **(Existence of a zero element of \wedge)** There is some $e \in \mathcal{R} \cup \{+\infty\}$, such that for all $a \in \mathcal{R} \cup \{+\infty\}$, $a \wedge e = a$.
- **(Idempotency of \wedge)** For all $a \in \mathcal{R} \cup \{+\infty\}$, $a \wedge a = a$.
- **(Commutativity of \wedge)** For all $a, b \in \mathcal{R} \cup \{+\infty\}$, $a \wedge b = b \wedge a$.
- **(Closure of $+$)** For all $a, b \in \mathcal{R} \cup \{+\infty\}$, $a + b \in \mathcal{R} \cup \{+\infty\}$.
- **(Zero element of \wedge is absorbing for $+$)** For all $a \in \mathcal{R} \cup \{+\infty\}$, $a + e = e = e + a$.
- **(Existence of neutral element for $+$)** There is some $u \in \mathcal{R} \cup \{+\infty\}$ such that for all $a \in \mathcal{R} \cup \{+\infty\}$, $a + u = a = u + a$.
- **(Distributivity of $+$ with respect to \wedge)** For all $a, b, c \in \mathcal{R} \cup \{+\infty\}$, $(a \wedge b) + c = (a + c) \wedge (b + c) = c + (a \wedge b)$

Wide-Sense Increasing Functions

Definition [wide-sense increasing]

A function is wide-sense increasing iff $f(s) \leq f(t)$ for all $s \leq t$.

- Define G as the set of non-negative wide-sense increasing functions.
- Define F as the set of non-negative wide-sense increasing functions with $f(t) = 0$ for $t < 0$.
- Operations on functions:
 - $(f + g)(t) = f(t) + g(t)$
 - $(f \wedge g)(t) = f(t) \wedge g(t)$

Wide-Sense Increasing Functions

- Peak rate function λ_R :
"Rate" R

$$\lambda_R(t) = \begin{cases} Rt & \text{if } t > 0 \\ 0 & \text{otherwise} \end{cases}$$

- Burst delay function δ_T :
"Delay" T

$$\delta_T(t) = \begin{cases} +\infty & \text{if } t > T \\ 0 & \text{otherwise} \end{cases}$$

Wide-Sense Increasing Functions (2)

- Rate latency function $\beta_{R,T}$:
 “Rate” R , “Delay” T

$$\beta_{R,T}(t) = \begin{cases} R(t-T) & \text{if } t > T \\ 0 & \text{otherwise} \end{cases}$$

- Affine functions $\gamma_{r,b}$:
 “Rate” r , “Burst” b

$$\gamma_{r,b}(t) = \begin{cases} rt + b & \text{if } t > 0 \\ 0 & \text{otherwise} \end{cases}$$

Wide-Sense Increasing Functions (3)

- Step function v_T :

$$v_T(t) = \begin{cases} 1 & \text{if } t > T \\ 0 & \text{otherwise} \end{cases}$$

- Staircase function $u_{T,\tau}$:
 “Interval” T , “Tolerance” τ

$$u_{T,\tau}(t) = \begin{cases} \left\lceil \frac{t+\tau}{T} \right\rceil & \text{if } t > 0 \\ 0 & \text{otherwise} \end{cases}$$

Wide-Sense Increasing Functions (4)

- More general functions in F can be constructed by combining basic functions.

- Example 1: $r_1 > r_2 > \dots > r_l$ and $b_1 < b_2 < \dots < b_l$

$$f_1 = \gamma_{r_1, b_1} \wedge \gamma_{r_2, b_2} \wedge \dots \wedge \gamma_{r_l, b_l} = \min_{1 \leq i \leq l} \{ \gamma_{r_i, b_i} \}$$

- Example 2:

$$f_2 = \lambda_R \wedge \{ \beta_{R, 2T} + RT \} \wedge \{ \beta_{R, 4T} + 2RT \} \wedge \dots$$

$$= \inf_{i \geq 0} \{ \beta_{R, 2iT} + iRT \}$$

Pseudo-Inverse of Wide-Sense Increasing Functions

Definition [Pseudo-inverse]

Let f be a function of F . The pseudo-inverse of f is the function $f^I(x) = \inf\{t \text{ such that } f(t) \geq x\}$.

- Examples:

$$\lambda_R^{-1} = \lambda_{1/R}$$

$$\delta_T^{-1} = \delta_0 \wedge T$$

$$\beta_{R,T}^{-1} = \gamma_{1/R,T}$$

$$\gamma_{r,b}^{-1} = \beta_{1/r,b}$$

Properties of Pseudo-Inverse

- **(Closure)**

$$f^{-1} \in F \text{ and } f^{-1}(0) = 0$$

- **(Pseudo-inversion)** We have that

$$f(t) \geq x \Rightarrow f^{-1}(x) \leq t$$

$$f^{-1}(x) < t \Rightarrow f(t) \geq x$$

- **(Equivalent definition)**

$$f^{-1}(x) = \sup\{t \text{ such that } f(t) < x\}$$

Min-Plus Convolution

- Integral of function $f(t)$ ($f(t) = 0$ for $t \leq 0$) in conventional algebra:

$$\int_0^t f(s) ds$$

- “Integral” for same function $f(t)$ in min-plus algebra:

$$\inf_{s \in \mathbb{R} \text{ such that } 0 \leq s \leq t} \{f(s)\}$$

- Convolution of two functions $f(t)$ and $g(t)$ that are zero for $t < 0$ in conventional algebra:

$$(f \otimes g)(t) = \int_0^t f(t-s) + g(s) ds$$

Definition [Min-plus convolution]

Let f and g be two functions of F . The min-plus convolution of f and g is the function

$$(f \otimes g)(t) = \inf_{0 \leq s \leq t} \{f(t-s) + g(s)\}$$

Min-Plus Convolution: Example 1

- Compute $(\gamma_{r,b} \otimes \beta_{R,T})(t)$

- Case 1: $0 \leq t \leq T$

$$\begin{aligned} (\gamma_{r,b} \otimes \beta_{R,T})(t) &= \inf_{0 \leq s \leq t} \{\gamma_{r,b}(t-s) + \beta_{R,T}(s)\} \\ &= \inf_{0 \leq s \leq t} \{\gamma_{r,b}(t-s) + 0\} = \gamma_{r,b}(0) + 0 = 0 \end{aligned}$$

- Case 2: $t > T$

$$\begin{aligned} (\gamma_{r,b} \otimes \beta_{R,T})(t) &= \inf_{0 \leq s \leq t} \{\gamma_{r,b}(t-s) + \beta_{R,T}(s)\} \\ &= \inf_{0 \leq s \leq T} \{\gamma_{r,b}(t-s) + \beta_{R,T}(s)\} \wedge \inf_{T \leq s \leq t} \{\gamma_{r,b}(t-s) + \beta_{R,T}(s)\} \wedge \inf_{s=t} \{\gamma_{r,b}(t-s) + \beta_{R,T}(s)\} \\ &= \inf_{0 \leq s \leq T} \{b + r(t-s) + 0\} \wedge \inf_{T \leq s \leq t} \{b + r(t-s) + R(s-T)\} \wedge \{0 + R(t-T)\} \\ &= \{b + r(t-T)\} \wedge \{b + r(t-T) + \inf_{T \leq s \leq t} \{(R-r)s\}\} \wedge \{R(t-T)\} \\ &= \{b + r(t-T)\} \wedge \{b + r(t-T)\} \wedge \{R(t-T)\} \\ &= \{b + r(t-T)\} \wedge \{R(t-T)\} \end{aligned}$$

Min-Plus Convolution: Example 1 (2)

Min-Plus Convolution: Example 2

$$\delta_T \otimes \lambda_R = ?$$

$$(\delta_T \otimes \lambda_R)(t) = \inf_{0 \leq s \leq t} \{\delta_T(t-s) + \lambda_R(s)\}$$

Case 1 ($0 \leq t \leq T$): $(\delta_T \otimes \lambda_R)(t) = \inf_{0 \leq s \leq t} \{\delta_T(t-s) + \lambda_R(s)\}$
 $= \inf_{0 \leq s \leq t} \{0 + \lambda_R(s)\} = 0$

Case 2 ($t > T$): $(\delta_T \otimes \lambda_R)(t) = (\lambda_R \otimes \delta_T)(t)$
 $= \inf_{0 \leq s \leq T} \{\lambda_R(t-s) + \delta_T(s)\}$
 $\wedge \inf_{T < s \leq t} \{\lambda_R(t-s) + \delta_T(s)\}$
 $= \inf_{0 \leq s \leq T} \{\lambda_R(t-s) + 0\} \wedge \inf_{T < s \leq t} \{\lambda_R(t-s) + \infty\}$
 $= \lambda_R(t-T) = \beta_{R,T}$

Models for Data Flow

- Consider system S : receives input data, and delivers data after a variable delay.
- $R(t)$ is cumulative input function at time t .
- $R^*(t)$ is cumulative output function at time t .

Definition [Backlog]

The backlog at time t is $R(t) - R^*(t)$.

Definition [Virtual Delay]

The virtual delay at time t is $d(t) = \inf\{\tau \geq 0 : R(t) \leq R^*(t + \tau)\}$

Virtual Delay

$$d(t) = \inf\{ \tau \geq 0 : R(t) \leq R^*(t + \tau) \}$$

- If input and output are continuous

$$R^*(t + d(t)) = R(t) \quad (*)$$

$$d(t) \text{ is smallest value satisfying } (*)$$

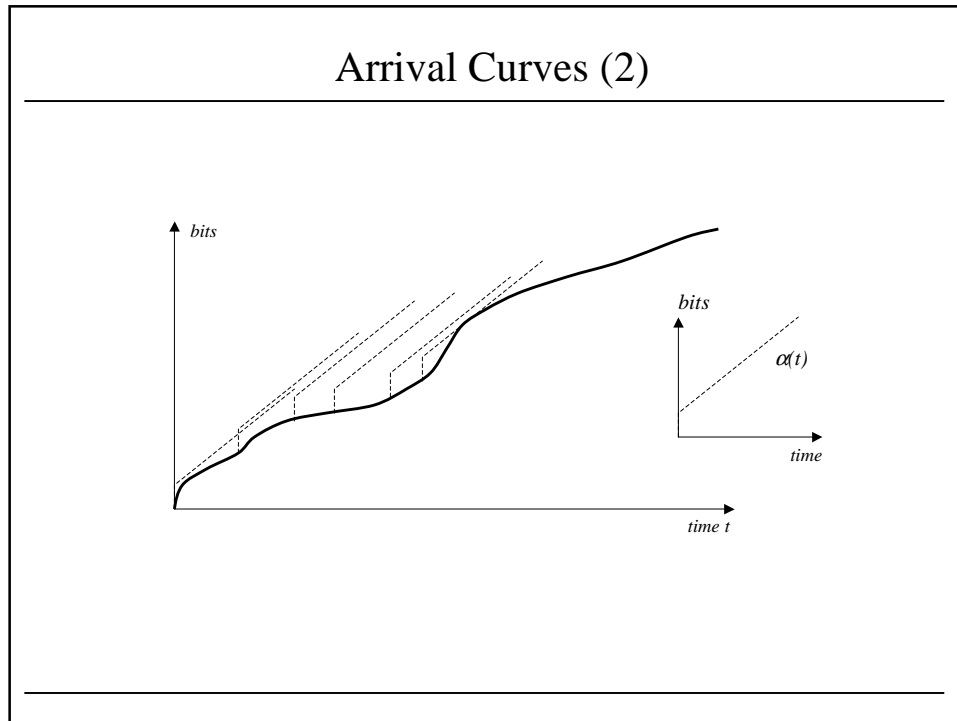

Arrival Curves

Definition [Arrival Curve $\alpha(\cdot)$]

Given a wide-sense increasing function $\alpha(\cdot)$ defined for $t \geq 0$ (i.e. $\alpha(\cdot) \in F$) we say that a flow R is constrained by $\alpha(\cdot)$ iff for all $s \leq t$:

$$R(t) - R(s) \leq \alpha(t - s).$$

- “R has $\alpha(\cdot)$ as arrival curve.”
- “R is bounded by $\alpha(\cdot)$.”
- “R is α -smooth.”
- Note:
 - $\alpha(\cdot)$ is in the interval-domain.
 - for all $s \geq 0$ and $I \geq 0$, $R(s + I) - R(s) \leq \alpha(I)$.

Example: Affine Arrival Curve $\gamma_{r,b}$

- $\alpha(t) = rt$ Flow is peak-rate limited. For example when physical bit rate is limited.
 - $\alpha(t) = b$ Maximum number of bits ever sent is at most b .
 - $\alpha(t) = rt + b$ Leaky bucket with rate r and burst tolerance b .
 - A leaky bucket constrains the arrival to the affine arrival curve $\gamma_{r,b} = rt + b$.
-

Example: Staircase Function $u_{T,\tau}$

Definition [Generic Cell Rate Algorithm $GCRA(T, \tau)$]

The Generic Cell Rate Algorithm (GCRA) with parameters (T, τ) is used with fixed size packets, called cells and defines conformant cells as follows: It takes as input a cell arrival time t and returns `result`. It has an internal (static) variable `tat` (theoretical arrival time).

```

- initially, tat = 0
- when a cell arrives at time  $t$ , then
  if ( $t < \text{tat} - \tau$ )
    result = NON-CONFORMANT
  else {
    tat =  $\max(t, \text{tat}) + T$ ;
    result = CONFORMANT;
  }

```

- For cells of size k , $GCRA(T, \tau)$ constrains flows to the staircase arrival function $k u_{T,\tau}(\cdot)$.

Equivalence of Leaky Bucket and GCRA

For a flow with packets of constant size δ , satisfying the $GCRA(T, \tau)$ is equivalent to satisfying a leaky bucket controller with rate r and burst tolerance b given by:

$$b = (\tau T + 1) \delta \quad \text{and} \quad r = \delta / T$$

Applications to ATM and Intserv:

- Constant Bit Rate (CBR) in ATM:
 - Single GCRA controller with parameters T (ideal cell interval) and τ (cell delay variation tolerance).
- Variable Bit Rate (VBR) in ATM:
 - Two GCRA controllers.
- Intserv: T-SPEC (p, M, r, b) with peak rate p , maximum packet size M , sustainable rate r , and burst tolerance b .

$$\alpha(t) = \min(M + pt, rt + b)$$

Sub-Additivity

Definition [Sub-additive function]

Let f be a function of F . Then f is sub-additive iff

$$f(t + s) \leq f(t) + f(s) \text{ for all } s, t \geq 0 .$$

- Notes:
 - If $f(0) = 0$, this is equivalent to imposing that $f = f \otimes f$.
 - Concave functions passing through origin are sub-additive.
 - While concavity and convexity are simple to check visually, sub-additivity is not.

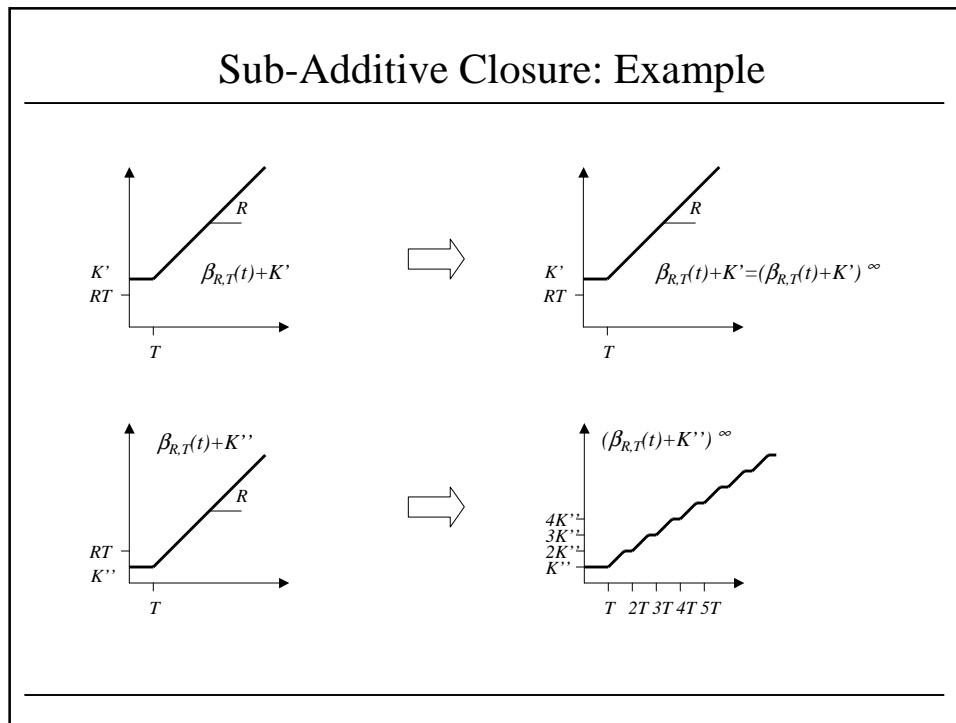

Sub-Additive Closure

Definition [Sub-additive closure]

Let f be a function of F . Denote $f^{(n)}$ the function obtained by repeating $(n-1)$ convolutions of f with itself. By convention, $f^{(0)} = \delta_0$, so that $f(1) = f$, $f(2) = f \otimes f$, etc. Then the sub-additive closure of f , denoted by f^∞ , is defined by

$$f^\infty = \delta_0 \wedge f \wedge (f \otimes f) \wedge (f \otimes f \otimes f) \wedge \dots = \inf_{n \geq 0} \{f^{(n)}\}$$

- The sub-additive closure is the largest sub-additive function smaller than f and zero in $t = 0$.

Sub-Additivity and Arrival Curves

Theorem: [Reduction of Arrival Curve to a Sub-Additive One]
 Saying that a flow is constrained by a wide-sense increasing function $\alpha(\cdot)$ is equivalent to saying that it is constrained by the sub-additive closure $\alpha^\infty(\cdot)$.

Lemma: A flow R is constrained by arrival curve α iff $R \leq R \otimes \alpha$.

Lemma: If α_1 and α_2 are arrival curves for a flow R , then so is $\alpha_1 \otimes \alpha_2$.

Min-Plus Deconvolution and Traffic Envelopes

Definition [Min-Plus Deconvolution]

Let f and g be two functions of F . The min-plus deconvolution of f by g is the function

$$(f \oslash g)(t) = \sup_{u \geq 0} \{f(t+u) - g(u)\}.$$

Definition [Minimum Arrival Curve – or Envelope]

The envelope of a flow R is defined by $R \oslash R$.

By definition, we have $(R \oslash R)(t) = \sup_{v \geq 0} \{R(t+v) - R(v)\}$.

Envelopes: Examples

(Figures from J.-Y. LeBoudec and Patrick Thiran: "Network Calculus: A Theory of Deterministic Queuing Systems for the Internet", Springer Verlag Lecture Notes in Computer Science)

Service Curves

Example 1: Generalized Processor Sharing (GPS)

- During any busy period (flow is backlogged) of length t , flow receives at least rt amount of service.
- Input flow $R(t)$, output flow $R^*(t)$, with t_0 being the beginning of busy period for flow.

$$R^*(t) - R^*(t_0) \geq r(t - t_0)$$

- At time t_0 , the backlog of flow is 0:

$$R(t_0) - R^*(t_0) = 0$$

- Therefore:

$$R^*(t) - R(t_0) \geq r(t - t_0)$$

- So:

$$R^*(t) \geq \inf_{0 \leq s \leq t} [R(s) + r(t - s)] \quad \Rightarrow \quad R^* \geq R \otimes \gamma_{r,0}$$

Service Curves

Example 2: Guaranteed-Delay Server

- Maximum delay for the bits of given flow R is bounded by some fixed value T , with bits of same flow served in FIFO order.

$$d(t) \leq T \quad \Leftrightarrow \quad R^*(t + T) \geq R(t)$$

- Can be re-written

$$R^*(s) \geq R(s - T) \quad \text{for all } s \geq T$$

- $R(s - T)$ can be re-written using “impulse function” δ_T :

$$(R \otimes \delta_T)(t) = R(t - T)$$

- Maximum delay condition can be formulated as

$$R^* \geq R \otimes \delta_T$$

Service Curve: Definition

(Figures from J.-Y. LeBoudec and Patrick Thiran: "Network Calculus: A Theory of Deterministic Queuing Systems for the Internet", Springer Verlag Lecture Notes in Computer Science)

The output R^* must be above $R \otimes \beta$, which is the lower envelope of all curves $t \rightarrow R(t_0) + \beta(t - t_0)$.

Definition [Service Curve]

Consider a system S and a flow through S with input and output function R and R^* . We say that S offers to the flow a service curve β iff $\beta \in F$ and $R^* \geq R \otimes \beta$.

Service Curves: Non-Preemptive Priority Node

- Let s be the beginning of busy period for high-priority traffic.
- Let l_{\max}^L be the maximum low-priority packet size.
- High-priority traffic:
- HP traffic can be blocked by a low-priority packet.

$$R_H^*(t) - R_H^*(s) \geq C(t - s) - l_{\max}^L$$
- By definition of s : $R_H^*(s) = R_H(s)$

$$R_H^*(t) \geq R_H(s) + C(t - s) - l_{\max}^L$$

$$R_H^*(t) \geq R_H(s) + \underbrace{\max\{0, C(t - s) - l_{\max}^L\}}_{\text{rate-latency function with rate } C \text{ and latency } l_{\max}^L/C}$$

Service Curves: Non-Preemptive Priority Node (2)

- Low-Priority Traffic:
- HP traffic is constrained by arrival function $\alpha_H(\cdot)$.
- Let s' be beginning of server busy period (note that $s' \leq s$).
- At time s' , backlogs for both flows are empty:

$$R_H^*(s') = R_H(s') \quad \text{and} \quad R_L^*(s') = R_L(s')$$
- Over $(s', t]$, the output is $C(t - s')$:

$$R_L^*(t) - R_L^*(s') = C(t - s') - [R_H^*(t) - R_H^*(s')]$$

$$\Rightarrow R_H^*(t) - R_H^*(s') = R_H^*(t) - R_H(s') \leq R_H(t) - R_H(s') \leq \alpha_H(t - s')$$
- $R_H^*(t) - R_H^*(s') \geq 0$

$$\Rightarrow R_L^*(t) - R_L(s') = R_L^*(t) - R_L^*(s') \geq \max\{0, C(t - s') - \alpha_H(t - s')\}$$

Network Calculus Basics: Backlog Bound

Theorem [Backlog Bound]

Assume a flow, constrained by arrival curve α , traverses a system that offers a service curve β . The backlog $R(t) - R^*(t)$ for all t satisfies:

$$R(t) - R^*(t) \leq \sup_{s \geq 0} \{\alpha(s) - \beta(s)\} = (\alpha \oslash \beta)(0) .$$

Network Calculus Basics: Delay Bound

Definition [Horizontal Deviation]

Let f and g be two functions of F . The horizontal deviation is defined as

$$h(f,g) = \sup_{t \geq 0} \{ \inf \{ d \geq 0 \text{ such that } f(t) \leq g(t + d) \} \}.$$

Horizontal deviation can be computed using pseudo inverse:

$$\begin{aligned} g^{-1}(f(t)) &= \inf \{ \Delta \text{ such that } g(\Delta) \geq f(t) \} \\ &= \inf \{ d \geq 0 \text{ such that } g(t + d) \geq f(t) \} + t \end{aligned}$$

$$\Rightarrow h(f,g) = \sup_{t \geq 0} \{ g^{-1}(f(t)) - t \} = (g^{-1}(f) \oslash \lambda_1)(0).$$

Theorem [Delay Bound]

Assume a flow, constrained by arrival curve α , traverses a system that offers a service curve of β . The virtual delay $d(t)$ for all t satisfies: $d(t) \leq h(\alpha, \beta)$.

Network Calculus Basic: Output Flow

Theorem [Output Flow]

Assume that a flow, constrained by arrival curve α , traverses a system that offers a service curve of β . The output flow is constrained by the arrival curve $\alpha^* = \alpha \oslash \beta$.

Network Calculus Basics: Concatenation

Theorem [Concatenation of Nodes]

Assume a flow traverses systems S_1 and S_2 in sequence. Assume that S_i offers a service curve of β_i , $i = 1, 2$ to the flow. Then the concatenation of the two systems offers a service curve of $\beta_1 \otimes \beta_2$ to the flow.

Proof:

- Call R_1 the output of node 1. This is also the input to node 2.

$$R_1 \geq R \otimes \beta_1$$

- and at node 2

$$R^* \geq R_1 \otimes \beta_2 \geq (R \otimes \beta_1) \otimes \beta_2 = R \otimes (\beta_1 \otimes \beta_2)$$

Example 1:

$$\beta_{R_1, T_1} \otimes \beta_{R_2, T_2} = \beta_{\min(R_1, R_2), T_1 + T_2}$$

Example 2: A rate-latency server can be described as $\beta_{R, T} = (\delta_T \otimes \lambda_R)(t)$. It can therefore be view as a concatenation of a guaranteed-delay node with delay T followed by a GPS node with rate R .
